

Serverless Data Processing with Dataflow

Agenda

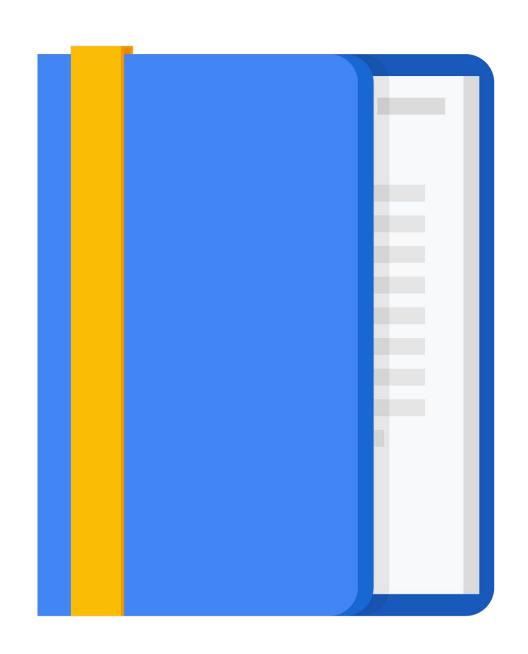

Cloud Dataflow

Why customers value Dataflow

Dataflow Pipelines

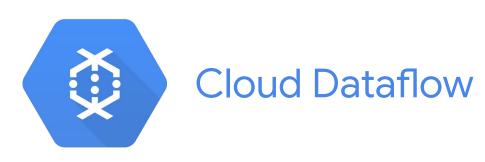

Dataflow Templates

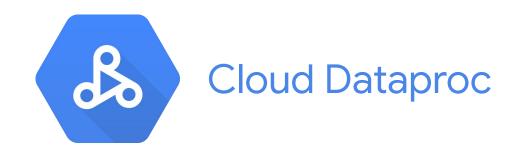

Dataflow SQL

Dataflow versus Dataproc

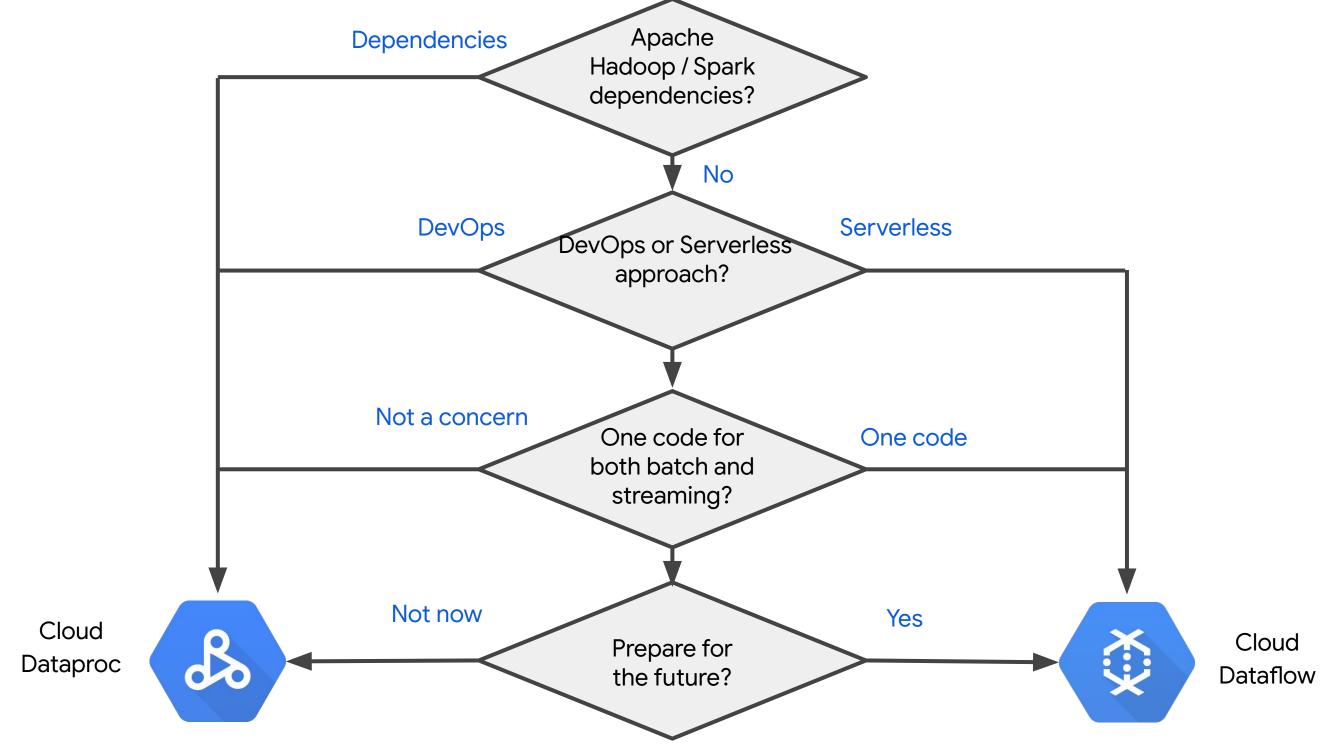

| | Recommended for: | New data processing pipelines, unified batch and streaming | Existing Hadoop/Spark applications, machine learning/data science ecosystem, large-batch jobs, preemptible VMs |
|--|------------------|--|--|
| | Fully-managed: | Yes | No |
| | Auto-scaling: | Yes, transform-by-transform (adaptive) | Yes, based on cluster utilization (reactive) |
| | Expertise: | Apache Beam | Hadoop, Hive, Pig, Apache Big Data ecosystem, Spark, Flink, Presto, Druid |

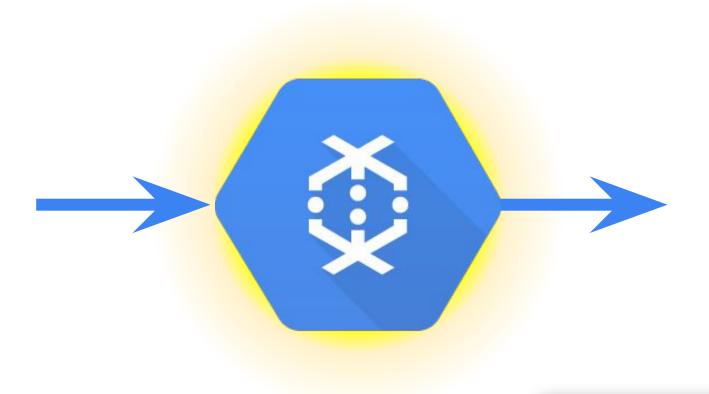

Choosing between Cloud Dataflow and Cloud Dataproc

Cloud Dataflow

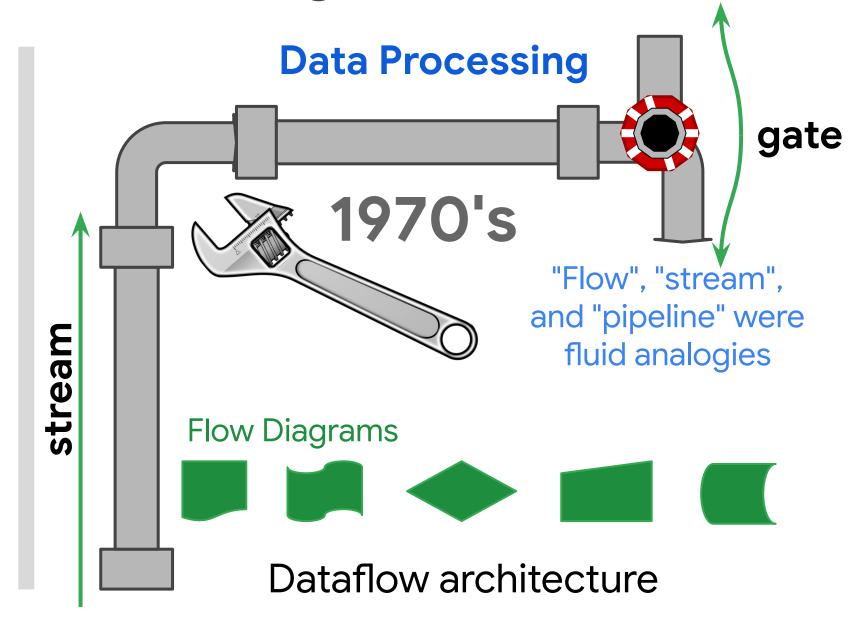

Cloud Dataflow Qualities that Cloud Dataflow contributes to Data Engineering solutions:

Scalability Low latency

Batch programming and data processing used to be two very separate and different things

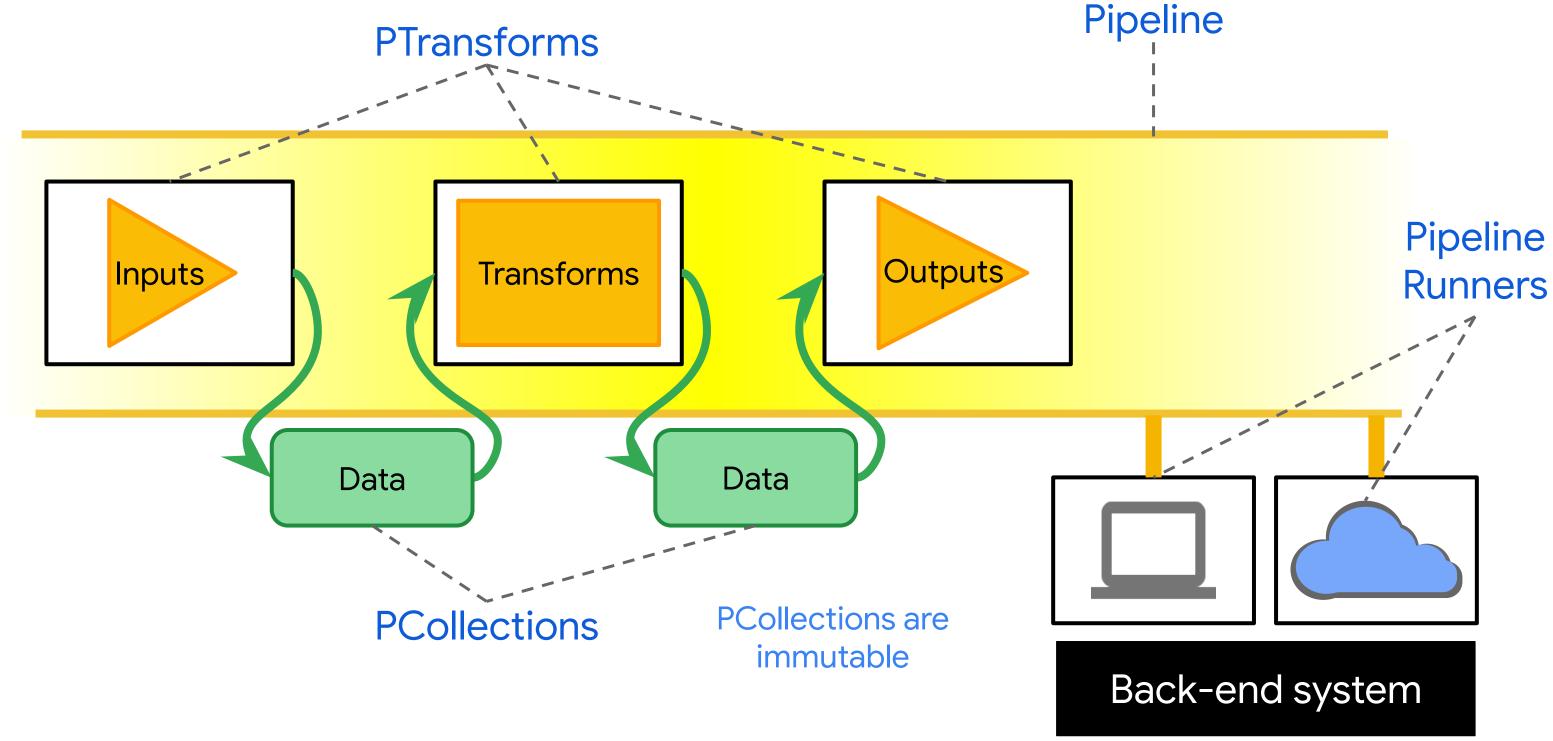

Batch Programming 1940's "Batch" originally referred to a batch or box of punch-cards code data Von Neumann architecture

Different tools, different platforms, different concepts, different methods.

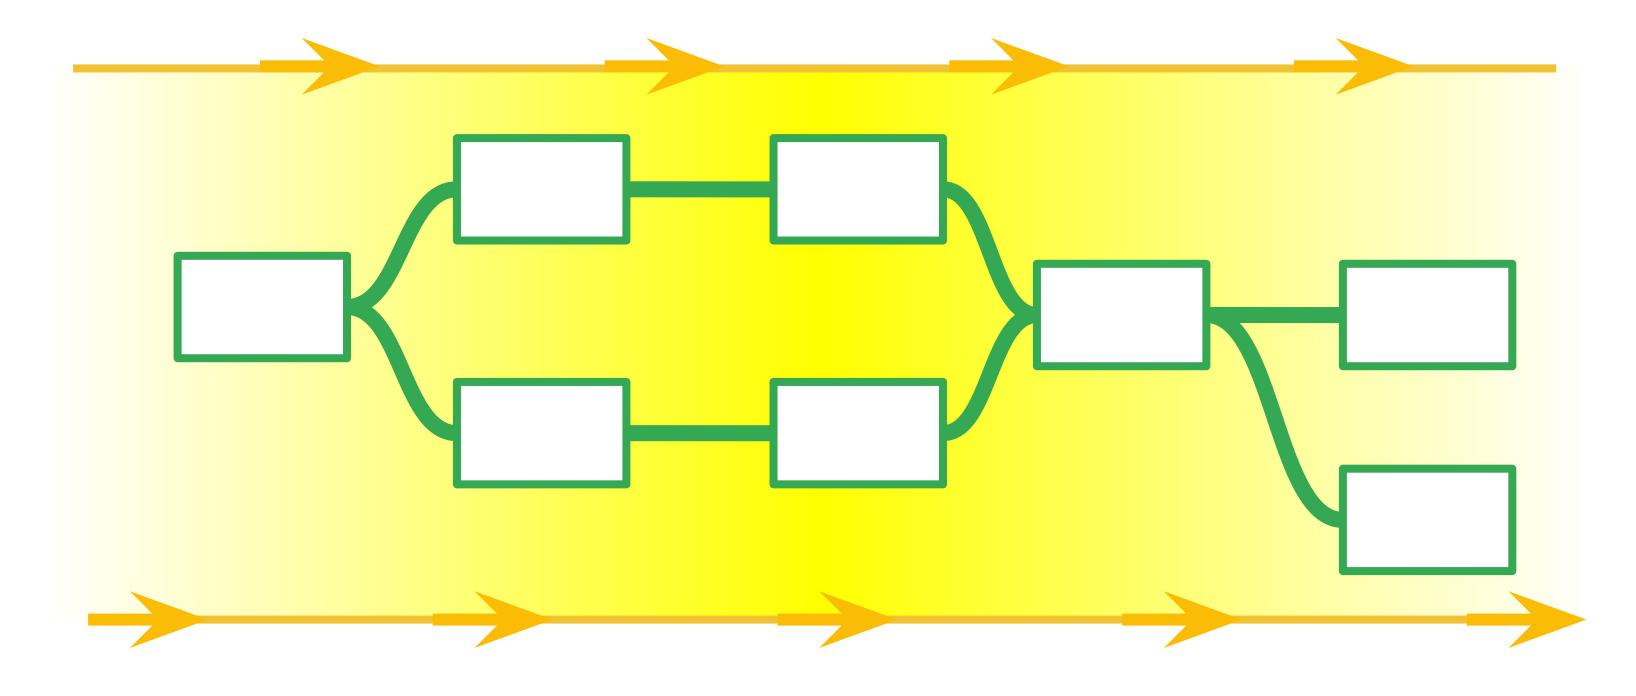

Apache BEAM = Batch + strEAM

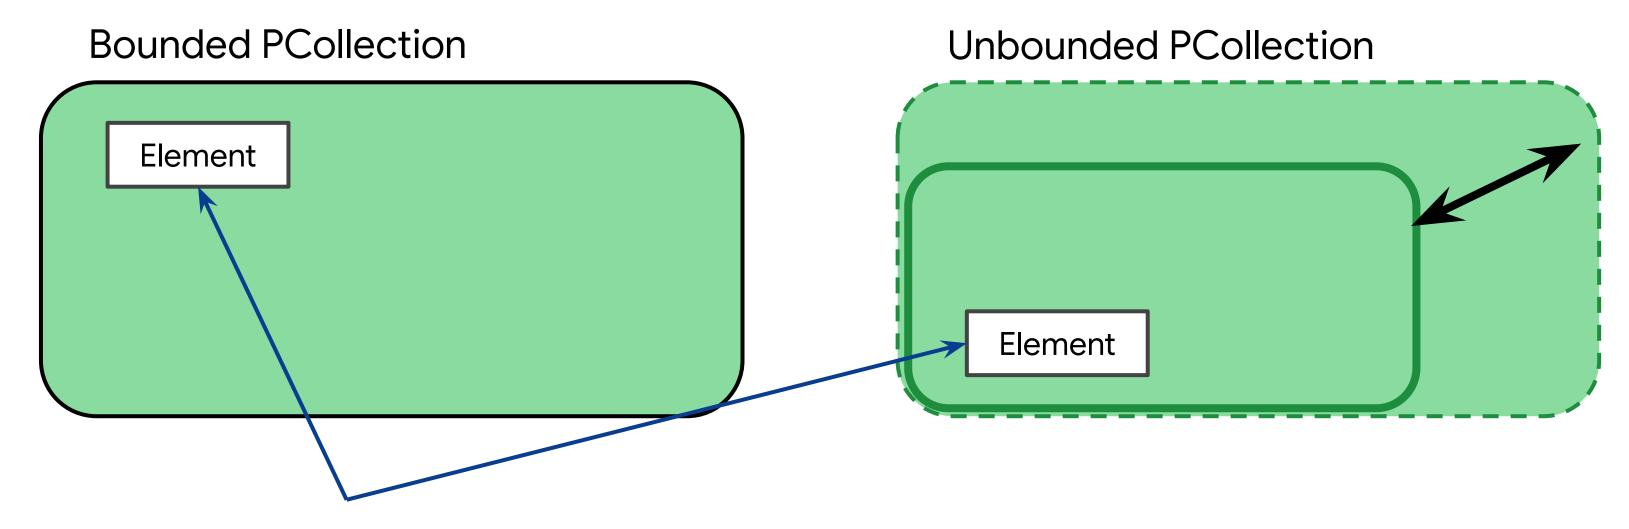

A Cloud Dataflow pipeline is a directed graph of steps

A PCollection represents batch or stream data

All data types are stored as serialized byte strings

Note: Bounded means the data has a fixed size not that the PCollection size is limited. A PCollection can be any size and be distributed across many workers.

Agenda

Cloud Dataflow

Why customers value Dataflow

Dataflow Pipelines

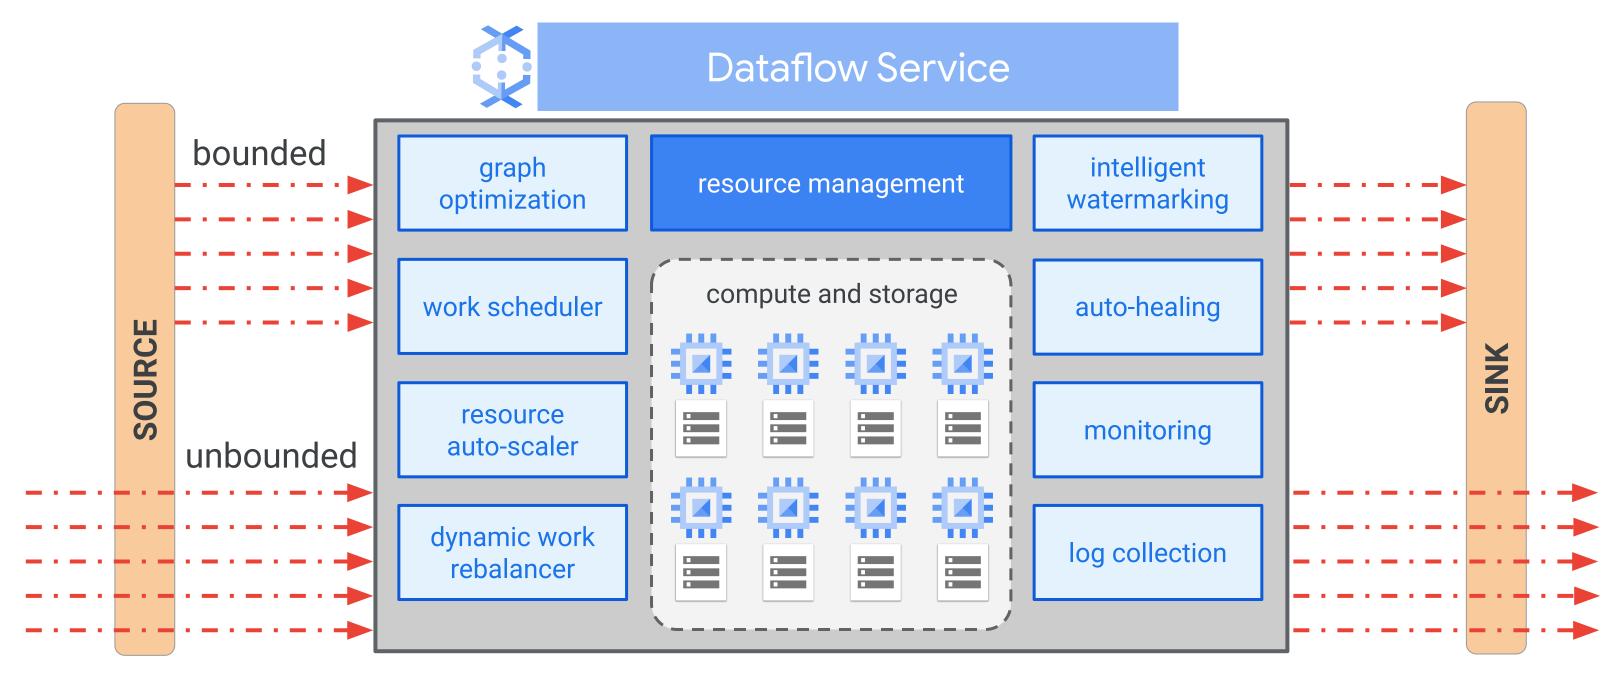

Dataflow Templates

Dataflow SQL

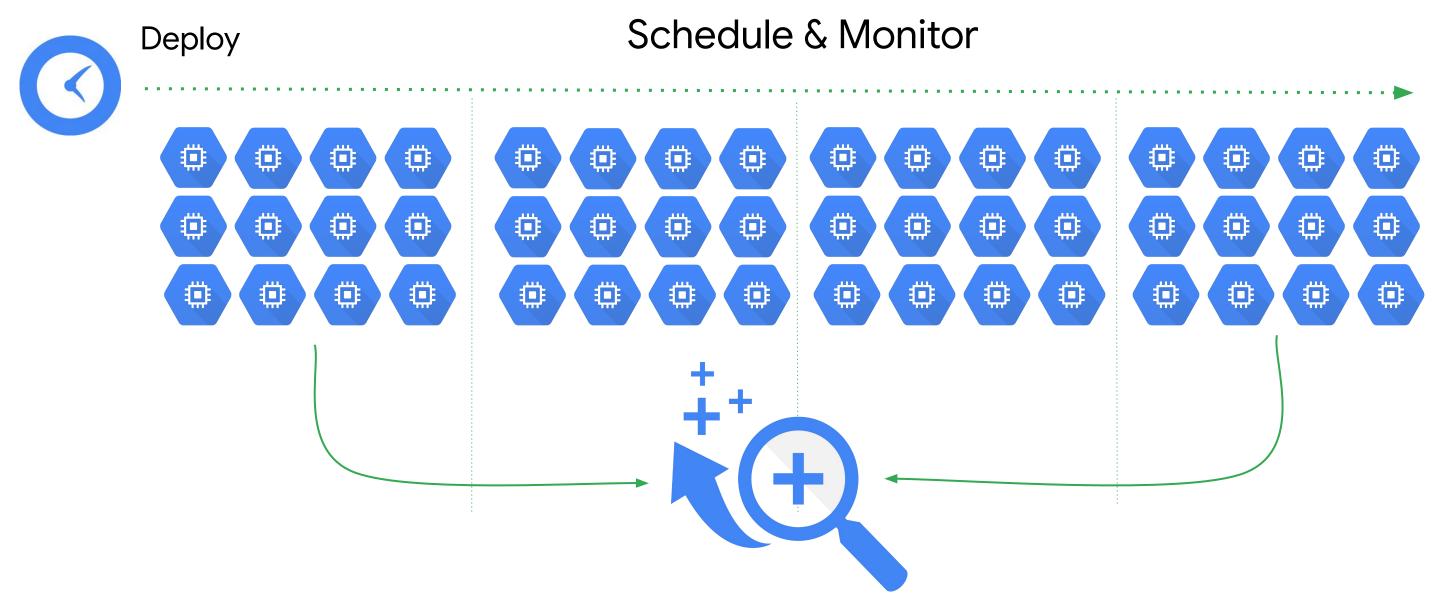

How does Dataflow work?

Dataflow constantly rebalances the work.

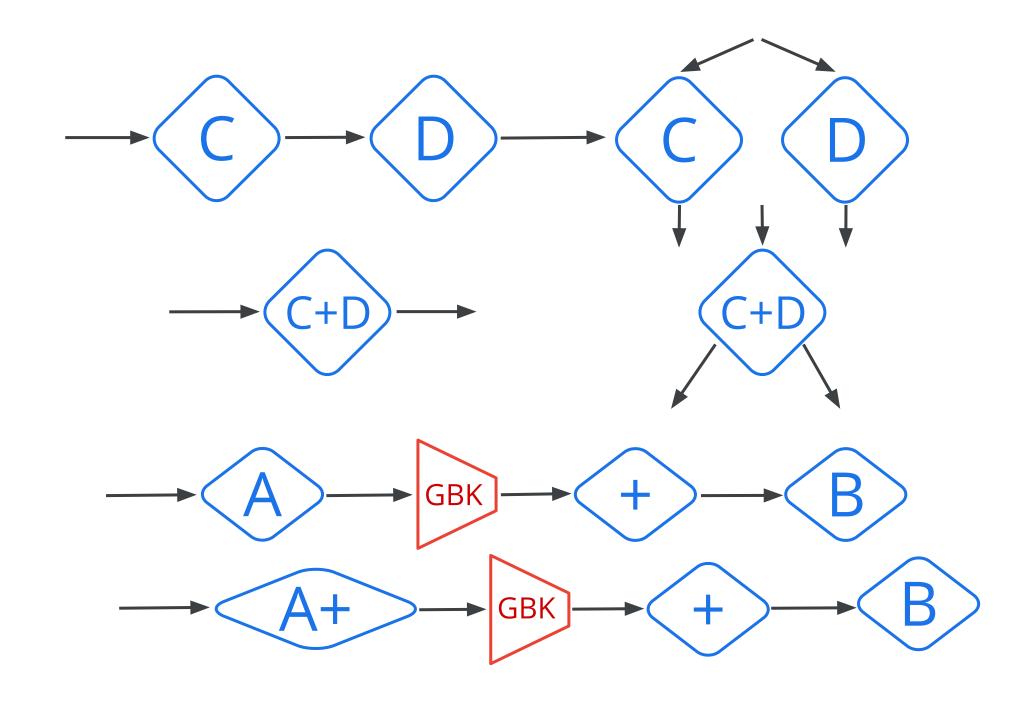

Why customers value Cloud Dataflow: Fully-managed and auto-configured

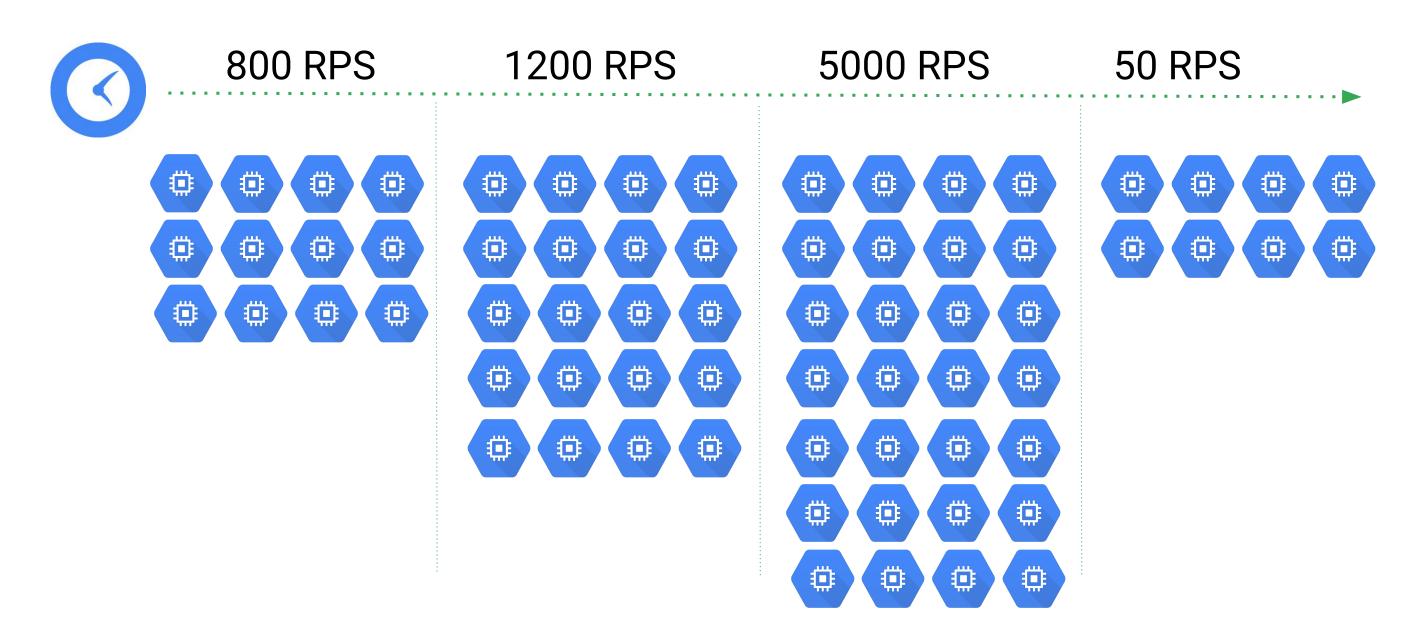

Why customers value Dataflow: Graph is optimized for best execution path

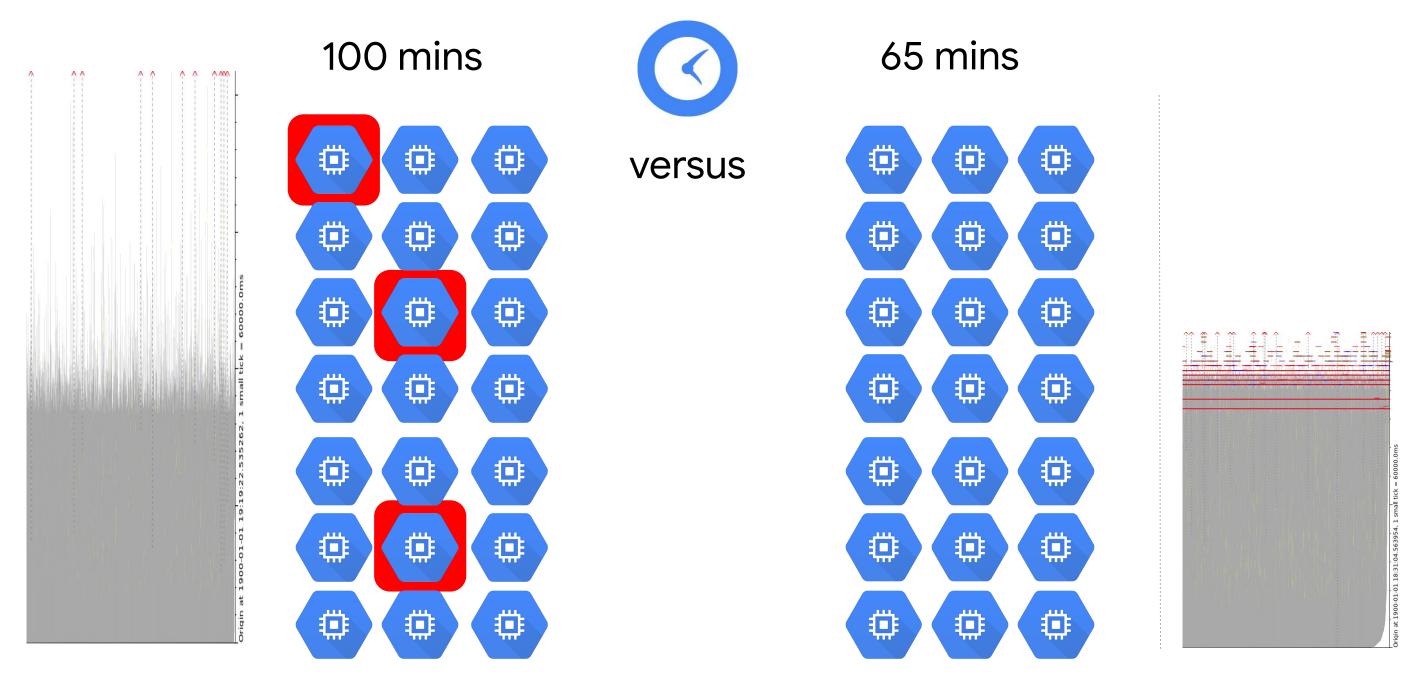

Why customers value Cloud Dataflow: Autoscaling mid-job

Why customers value Cloud Dataflow: Dynamic work rebalancing mid-job

Why customers value Cloud Dataflow: Strong streaming semantics

Exactly once aggregations

Rich time tracking

Good integration with other GCP services

Agenda

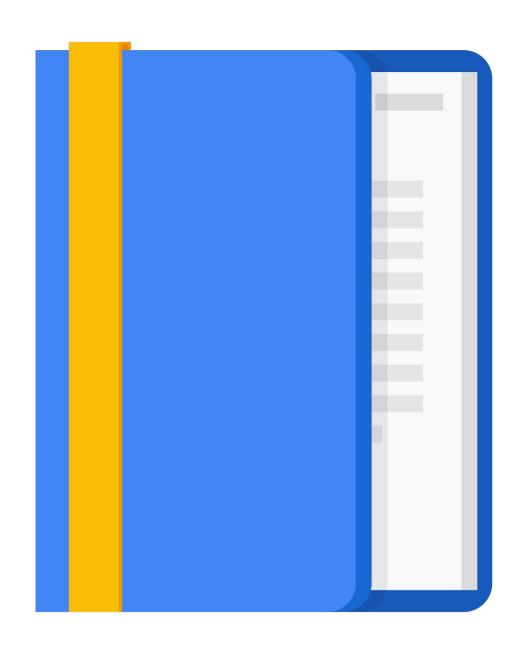

Cloud Dataflow

Why customers value Dataflow

Dataflow Pipelines

Dataflow Templates

Dataflow SQL

How to construct a simple pipeline

Python

Python overloads the pipe operator

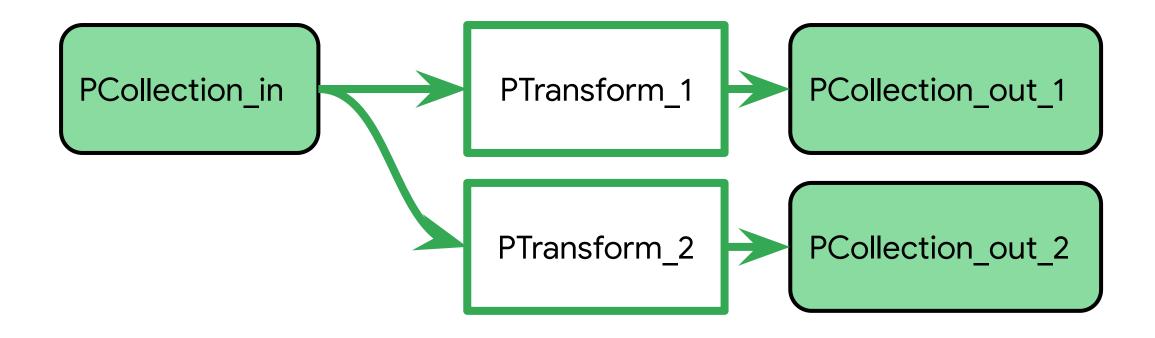

Java

Java uses the .apply method

```
PCollection_out = PCollection_in.apply(PTransform_1)
.apply(PTransform_2)
.apply(PTransform_3)
```

How to construct a branching pipeline

```
PCollection_out_1 = PCollection_in | PTransform_1
PCollection_out_2 = PCollection_in | PTransform_2

Python
```

Java

```
PCollection_out_1 = PCollection_in.apply(PTransform_1)
PCollection_out_2 = PCollection_in.apply(PTransform_2)
```

A Pipeline is a directed graph of steps

```
Python
import apache_beam as beam
                                    Create a pipeline
                                    parameterized by
if __name__ == '__main__':
                                    command line flags
  with beam.Pipeline(argv=sys.argv) as p:
       (p
           beam.io.ReadFromText('gs://...') ◀------Read input
           beam.FlatMap(lambda line: count_words(line)) ←-- Apply transform
          # end of with-clause: runs, stops the pipeline
```

Run a pipeline on Cloud Dataflow

Pipeline Execution using DataflowRunner

Run local

```
python ./grep.py
```

Run on cloud

```
python ./grep.py \
    --project=$PROJECT \
    --job_name=myjob \
    --staging_location=gs://$BUCKET/staging/ \
    --temp_location=gs://$BUCKET/tmp/ \
    --runner=DataflowRunner
```

Designing Pipelines

- . Input and Output
- . PTransforms

Read data from local file system, Cloud Storage, Pub/Sub, BigQuery, ...

```
with beam.Pipeline(options=pipeline_options) as p:
```

Read from Cloud Storage (returns a string)

```
lines = p | beam.io.ReadFromText("gs://.../input-*.csv.gz")
```

Read from Pub/Sub (returns a string)

```
lines = p | beam.io.ReadStringsFromPubSub(topic=known_args.input_topic)
```

Read from BigQuery (returns rows)

Write to a BigQuery table

Establish reference to BigQuery table

```
from apache_beam.io.gcp.internal.clients import bigquery

table_spec = bigquery.TableReference(
    projectId='clouddataflow-readonly',
    datasetId='samples',
    tableId='weather_stations')
```

Write to BigQuery table

```
p | beam.io.WriteToBigQuery(
    table_spec,
    schema=table_schema,
    write_disposition=beam.io.BigQueryDisposition.WRITE_TRUNCATE,
    create_disposition=beam.io.BigQueryDisposition.CREATE_IF_NEEDED)
```

Create a PCollection from in-memory data

```
city_zip_list = [
    ('Lexington', '40513'),
    ('Nashville', '37027'),
    ('Lexington', '40502'),
    ('Seattle', '98125'),
    ('Mountain View', '94041'),
    ('Seattle', '98133'),
    ('Lexington', '40591'),
    ('Mountain View', '94085'),
]
citycodes = p | 'CreateCityCodes' >> beam.Create(city_zip_list)
```

PCollection

Designing Pipelines

- . Input and Output
- . PTransforms

Map and FlatMap

Use Map for 1:1 relationship between input and output

```
'WordLengths' >> beam.Map( lambda word: (word, len(word)) )
```

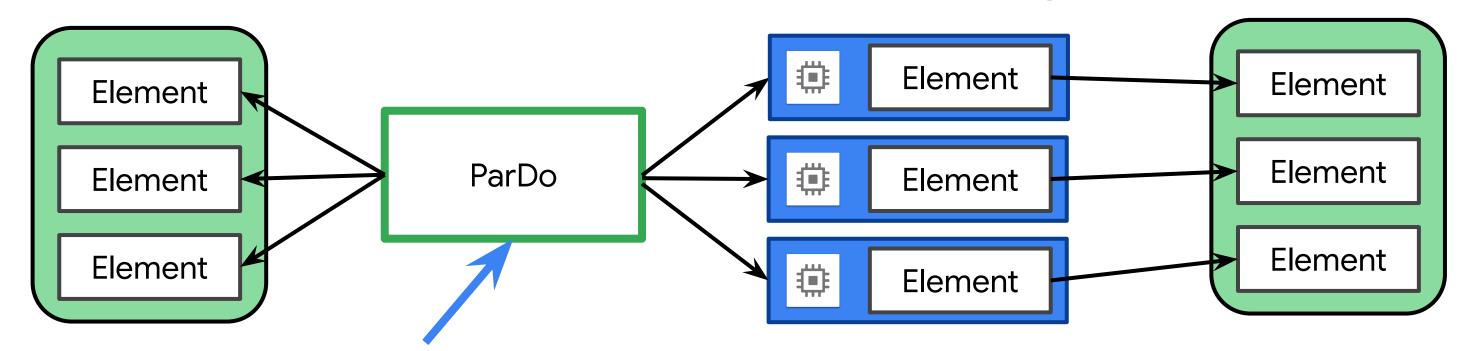

Map (fn) uses a callable fn to do a one-to-one transformation.

Use FlatMap for non 1:1 relationships, usually with a generator

FlatMap is similar to Map, but fn returns an iterable of zero or more elements. The iterables are flattened into one PCollection.

ParDo implements parallel processing

ParDo acts on one item at a time in the PCollection Multiple instances of class on many machines Should not contain any state

Uses:

Filtering a data set, choosing which elements to output.

Formatting or type-converting each element in a data set.

Extracting parts of each element in a data set.

Performing computations on each element in a data set.

ParDo requires code passed as a DoFn object

```
Python
words = ...

class ComputeWordLengthFn(beam.DoFn): <----------------DoFN
  def process(self, element):
    return [len(element)]

word_lengths = words | beam.ParDo(ComputeWordLengthFn())</pre>
```

The input is a PCollection of strings.

The DoFn to perform on each element in the input PCollection.

The output is a PCollection of integers.

Apply a ParDo to the PCollection "words" to compute lengths for each word.

ParDo method can emit multiple variables

```
results = (words | beam.ParDo(ProcessWords(), cutoff_length=2, marker='x')
    .with_outputs('above_cutoff_lengths', 'marked strings', main='below_cutoff_strings'))

below = results.below_cutoff_strings
    above = results.above_cutoff_lengths
    marked = results['marked strings']
```

A Simple Dataflow Pipeline (Python/Java)

Objectives

- Open Dataflow project
- Pipeline filtering
- Execute the pipeline locally and on the cloud

GroupByKey explicitly shuffles key-values pairs

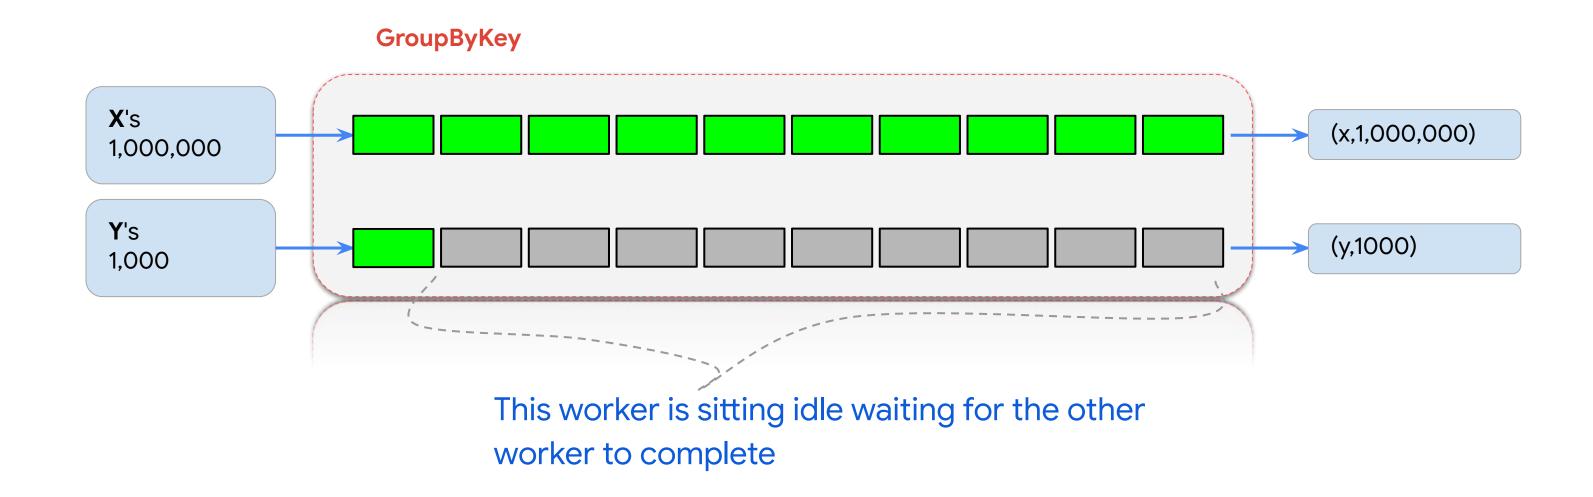

```
cityAndZipcodes = p | beam.Map(lambda fields: (fields[0], fields[1]))
grouped = cityAndZipCodes | beam.GroupByKey()
```

```
Lexington, 40513
Nashville, 37027
Lexington, 40502
Seattle, 98125
Mountain View, 94041
Seattle, 98133
Lexington, 40591
Mountain View, 94085

Lexington, [40513, 40502, 40592]
Nashville, [37027]
Seattle, [98125, 98133]
Mountain View, [94041, 94085]
```

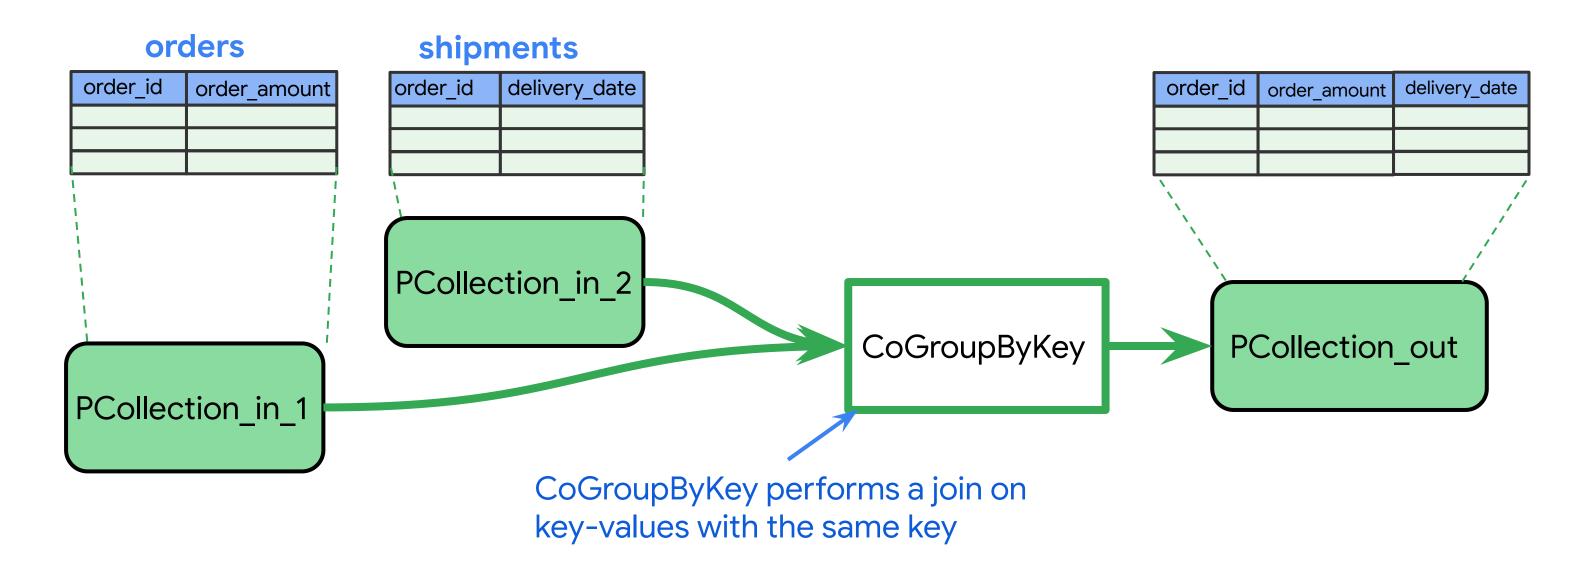

Data skew makes grouping less efficient at scale

CoGroupByKey joins two or more key-value pairs

Combine (reduce) a PCollection

Applied to a PCollection of values

```
totalAmount = salesAmounts | CombineGlobally(sum)
```

Applied to a grouped Key-Value pair

totalSalesPerPerson = salesRecords | CombinePerKey(sum)

Each element of salesRecords is a tuple: (salesPerson, salesAmount)

Pre-built combine functions for many common numeric combination operations such as sum, mean, min, and max

CombineFn works by overriding existing operations

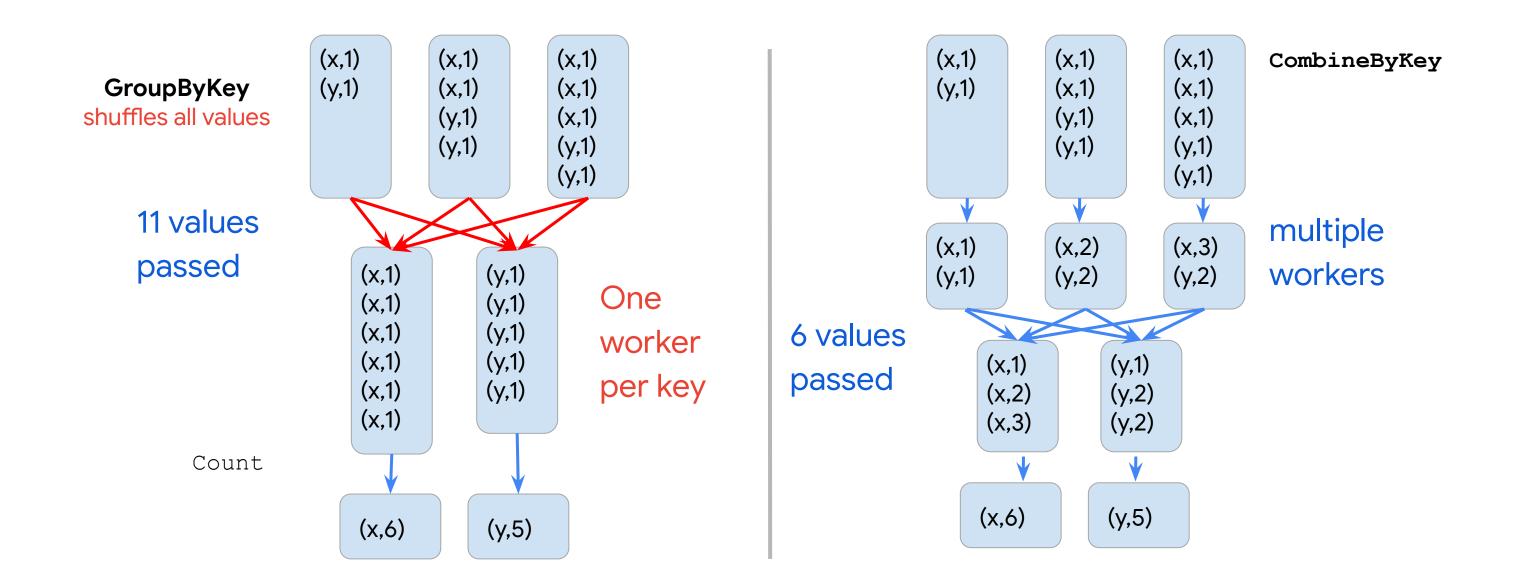

You must provide four operations by overriding the corresponding methods

```
class AverageFn (beam.CombineFn):
  def create accumulator(self):
    return (0.0, 0)
 def add input(self, sum count, input):
    (sum, count) = sum count
    return sum + input, count + 1
  def merge accumulators (self, accumulators):
    sums, counts = zip(*accumulators)
    return sum(sums), sum(counts)
 def extract output (self, sum count):
    (sum, count) = sum count
    return sum / count if count else float('NaN')
```

```
pc = ...
average = pc | beam.CombineGlobally(AverageFn())
```

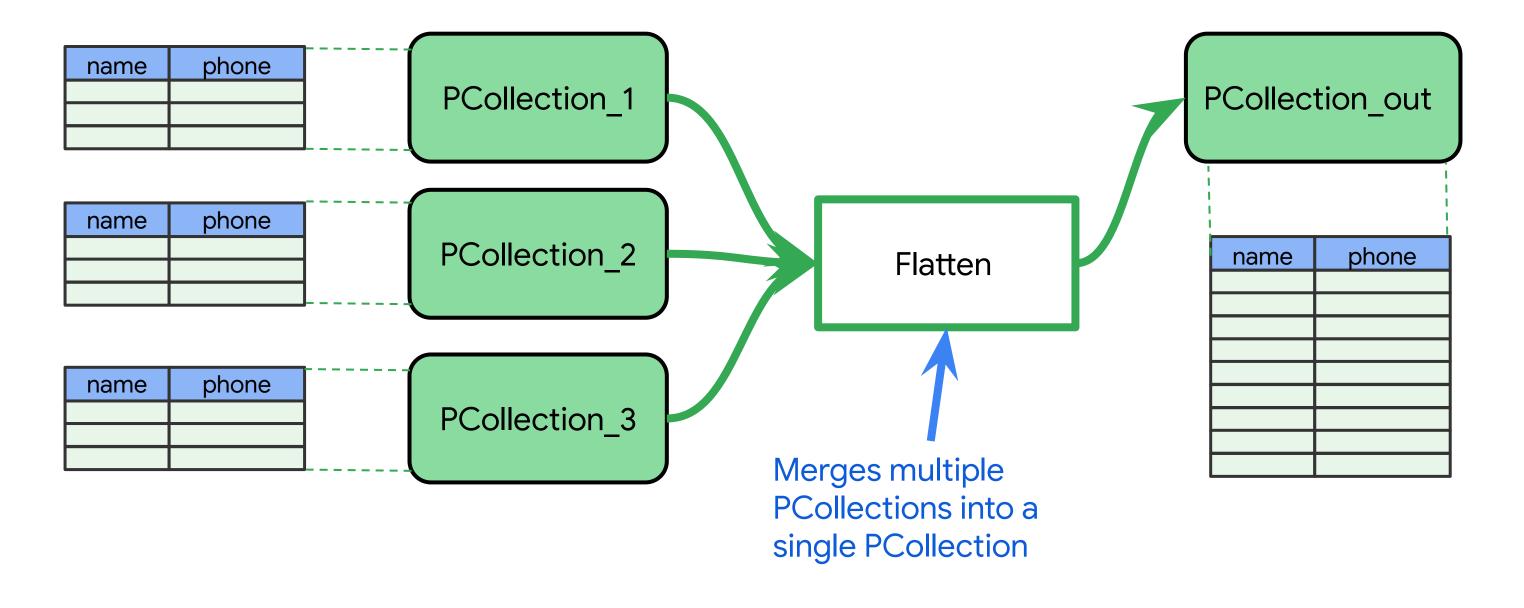

Combine is more efficient than GroupByKey

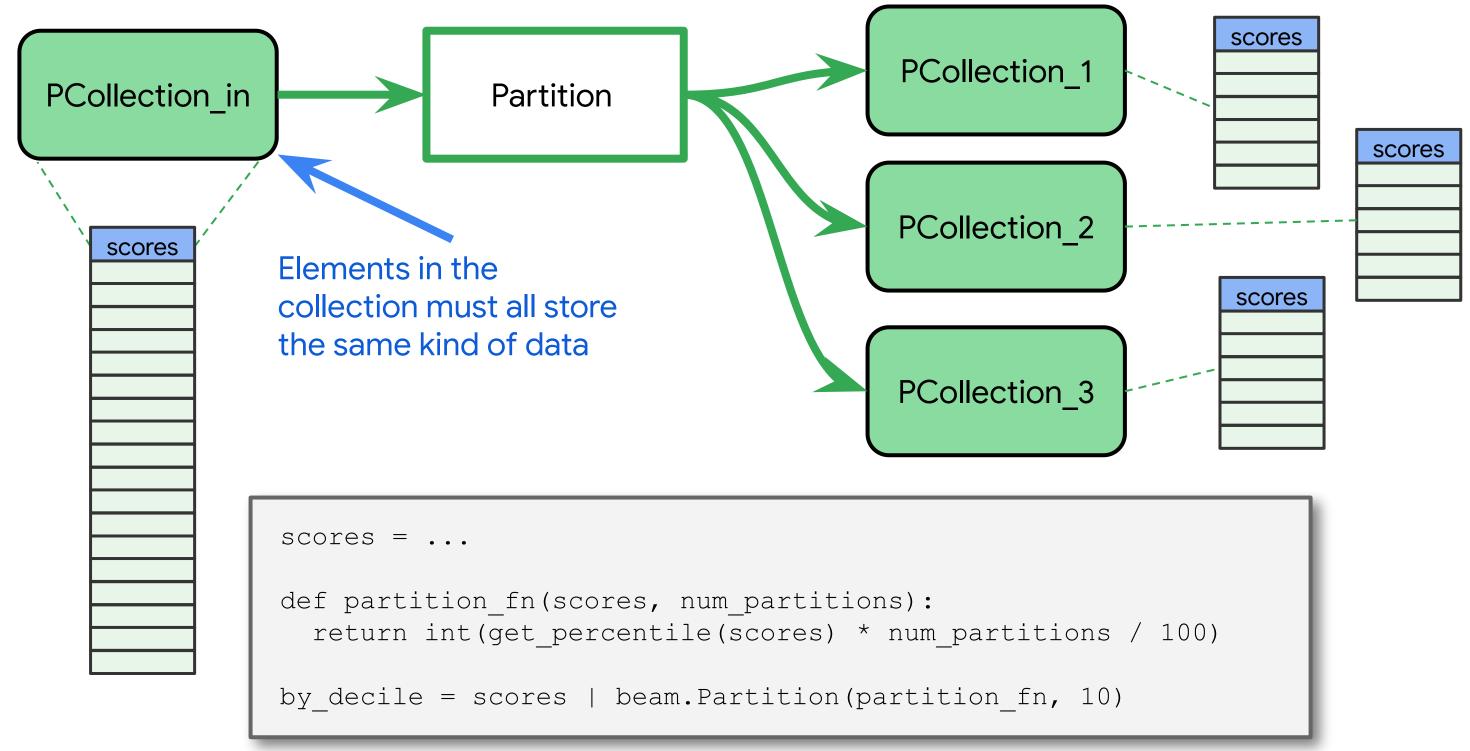

Flatten merges identical PCollections

merged = ((pcoll1, pcoll2, pcoll3) | beam.Flatten())

Partition splits PCollections into smaller PCollections

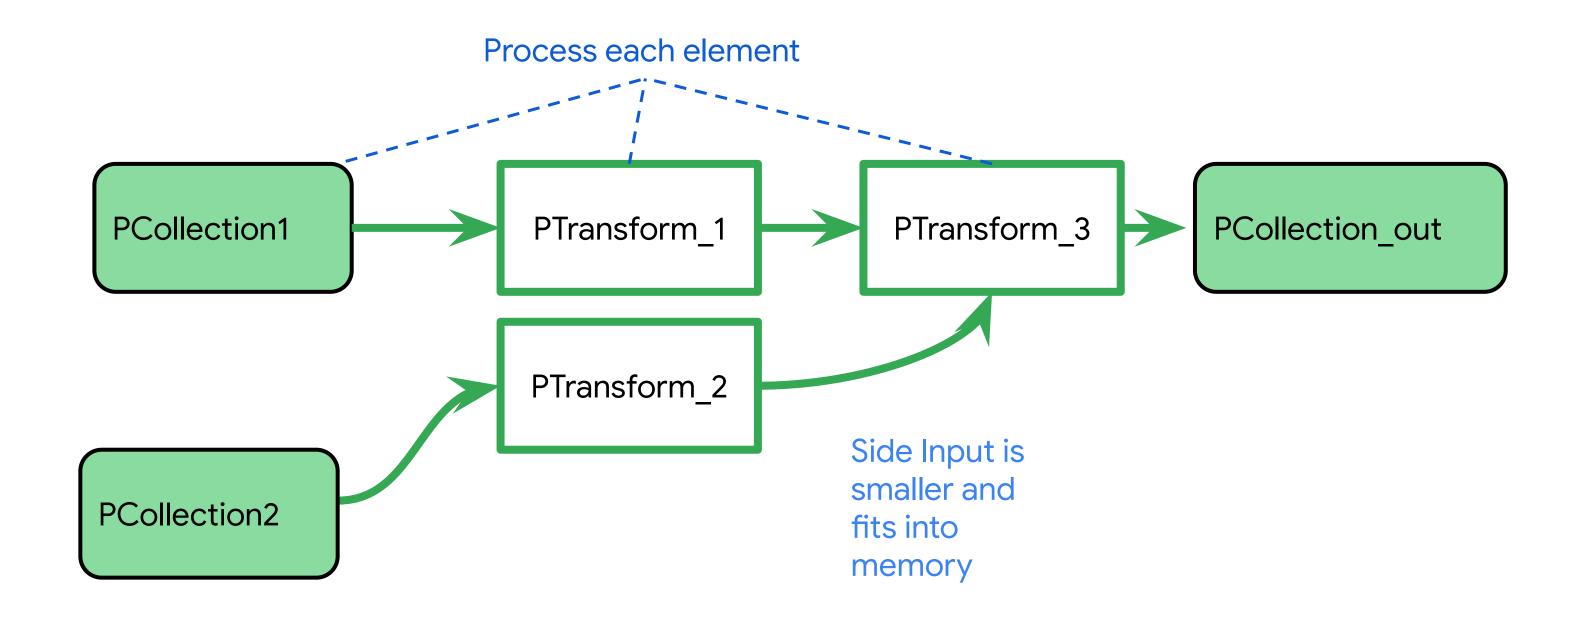

MapReduce in Dataflow (Python/Java)

Objectives

- Identify Map and Reduce operations
- Execute the pipeline
- Use command line parameters

Use side inputs to inject additional runtime data

How side inputs work

```
words = ...
def filter using length(word, lower bound, upper bound=float('inf')):
 if lower bound <= len(word) <= upper bound:</pre>
    yield word
small words = words | 'small' >> beam.FlatMap(filter using length, 0, 3)
avg word len = (words
                 beam.Map(len)
                  beam.CombineGlobally(beam.combiners.MeanCombineFn()))
larger than average = (words | 'large' >> beam.FlatMap(
    filter using length,
    lower bound=pvalue.AsSingleton(avg word len))) <
```

Side input

Side Inputs (Python/Java)

Objectives

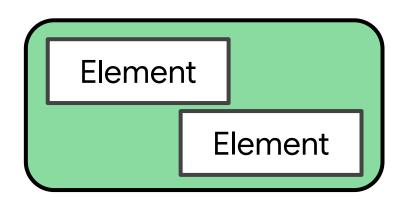

- Try out a BigQuery query
- Explore the pipeline code
- Execute the pipeline

Processing Time-series data using Windowing

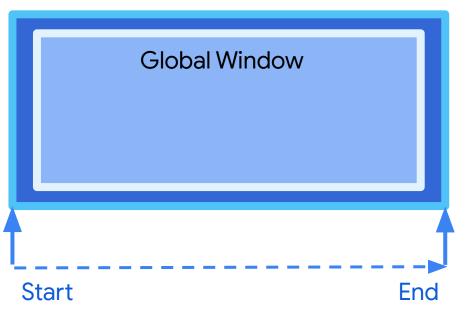

Every PCollection is processed within a Window

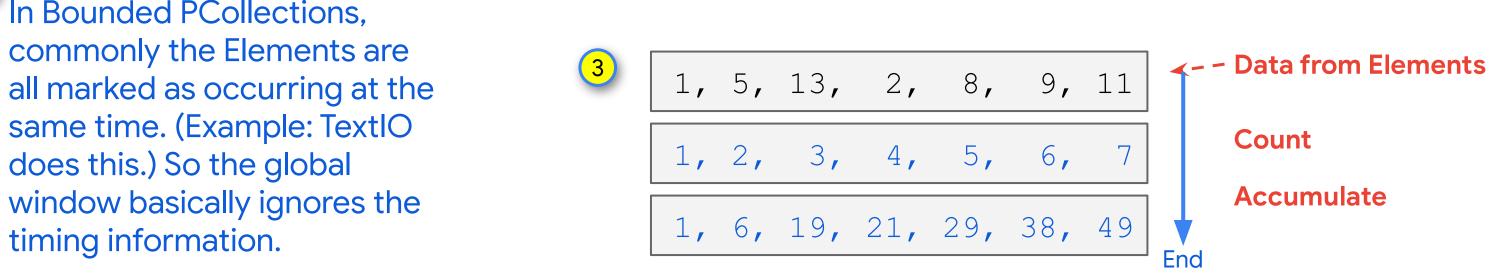

Bounded PCollection

In Bounded PCollections. commonly the Elements are same time. (Example: TextlO does this.) So the global window basically ignores the timing information.

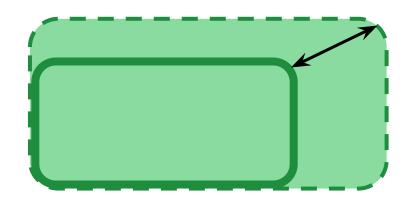

The default window is called the global window, it starts when the data is input and ends when the last element in the collection is processed.

$$49/7 = 7$$
 Completion

The global window is not very useful for an unbounded PCollection

Unbounded PCollection

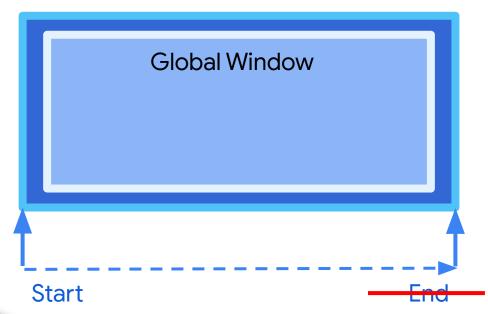

1

The timing associated with the elements in an Unbounded PCollection is usually important to processing the data.

The discussion about Unbounded PCollections and Windows will be continued in the course on Processing Streaming Data.

An Unbounded PCollection has no defined end or last element. So it can never perform the completion step.

This is particularly important for **GroupByKey** and **Combine**, which perform the shuffle after 'end'.

Setting a single global window for a PCollection.

Single global window

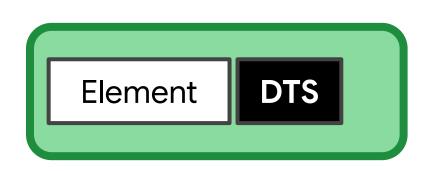

```
from apache_beam import window
session_windowed_items = (
   items | 'window' >> beam.WindowInto(window.GlobalWindows()))
```

This is the default.

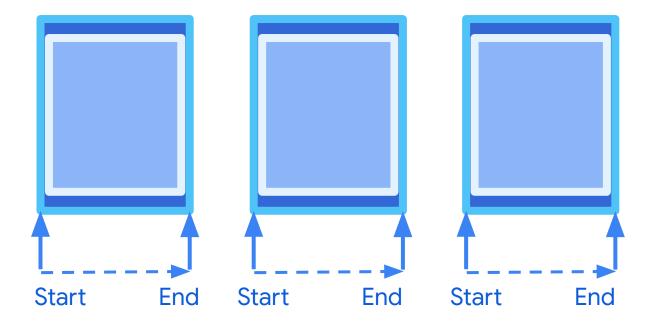

This code illustrates how you could explicitly set it.

Time-based Windows can be useful for processing time-series data

You may have to prepare the date-timestamp. In this example, the dts of the data (log writing time) becomes the element time. Now the elements have different times from one another.

2

Using time based windowing the data is processed in groups.

In the example, each group gets its own average.

3

There are different kinds of windowing.

Shown is "Fixed" There is also "Sliding" and "Session".

Using Windowing with Batch (group by time)

```
lines = p | 'Create' >> beam.io.ReadFromText('access.log')
windowed_counts = (
    lines
    | 'Timestamp' >> beam.Map(lambda x: beam.window.TimestampedValue(x, extract_timestamp(x)))
    | 'Window' >> beam.WindowInto(beam.window.SlidingWindows(60, 30))
    | 'Count' >> (beam.CombineGlobally(beam.combiners.CountCombineFn()).without_defaults())
)
windowed_counts = windowed_counts | beam.ParDo(PrintWindowFn())
```

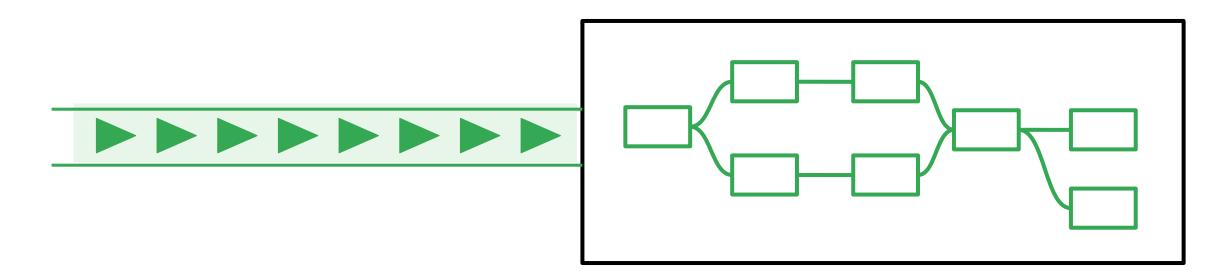

access.log (example)

```
131.108.5.17 - - [29/Apr/2019:04:53:15 -0800] "GET /view HTTP/1.1" 200 7352
131.108.5.17 - - [29/Apr/2019:05:21:35 -0800] "GET /view HTTP/1.1" 200 5253
```

Date Time Stamp

Streaming data processing with Cloud Dataflow

Discussion of streaming continues in the Streaming Data Processing course.

Agenda

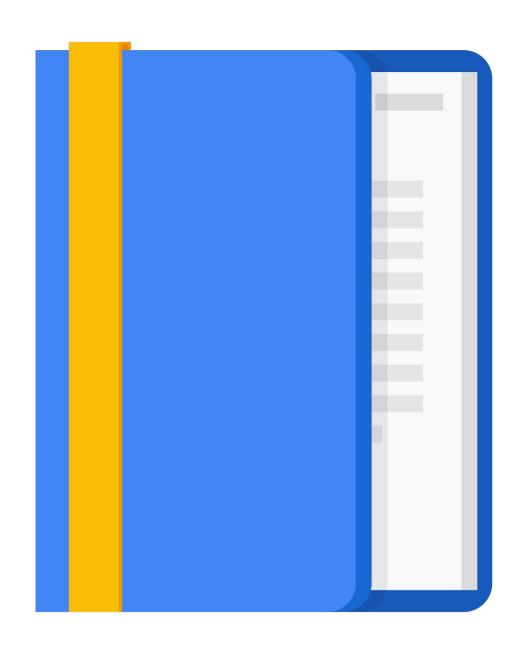

Cloud Dataflow

Why customers value Dataflow

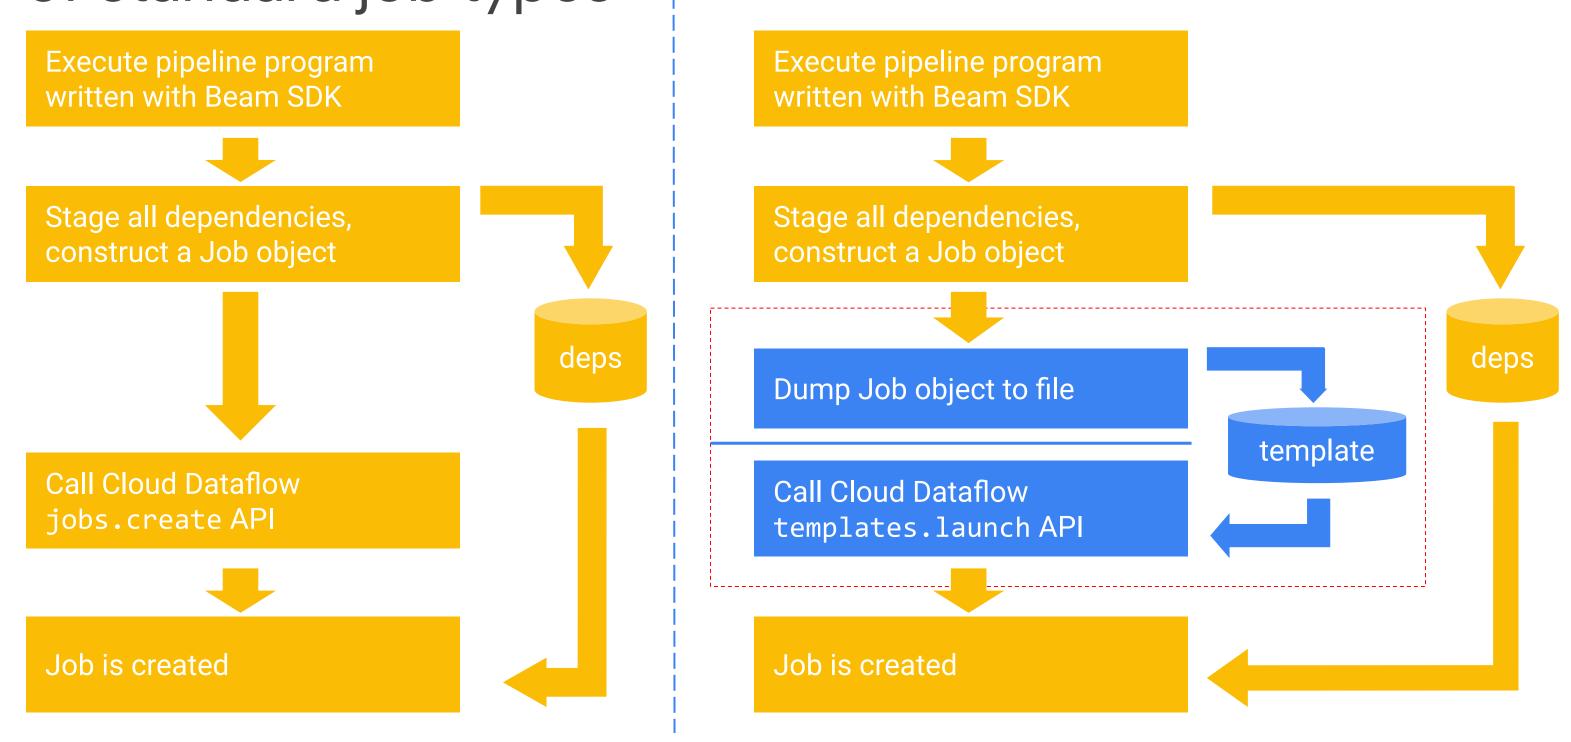

Dataflow Pipelines

Dataflow Templates

Dataflow SQL

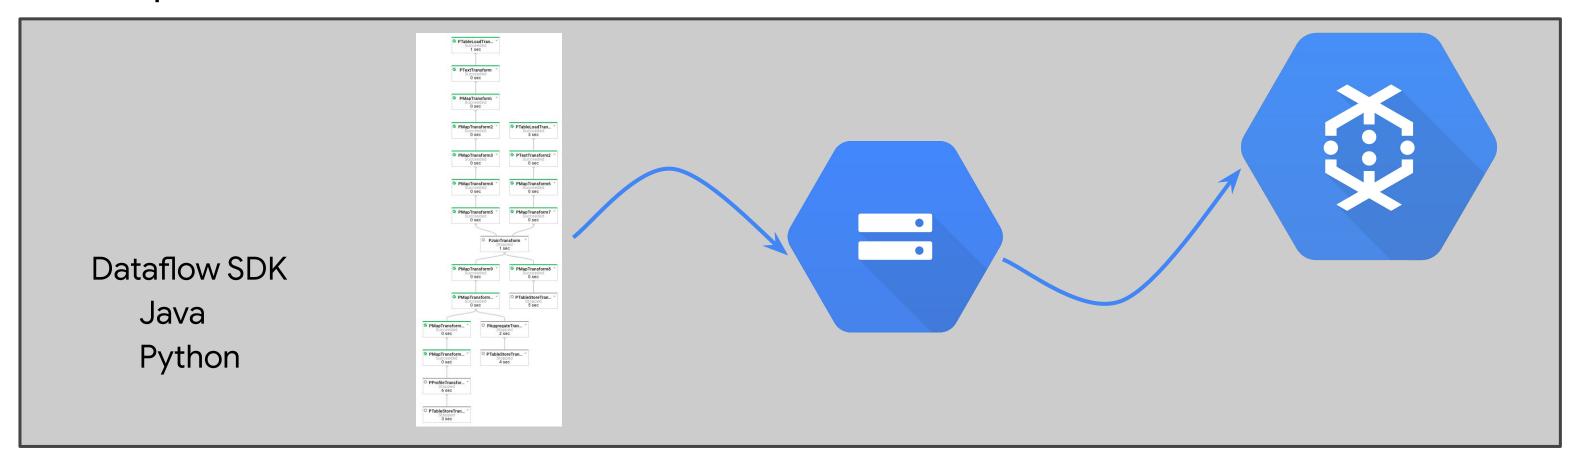

Cloud Dataflow templates enable the rapid deployment of standard job types

Traditional workflow all happens in one environment

Development environment

Developer executes pipeline on Dataflow

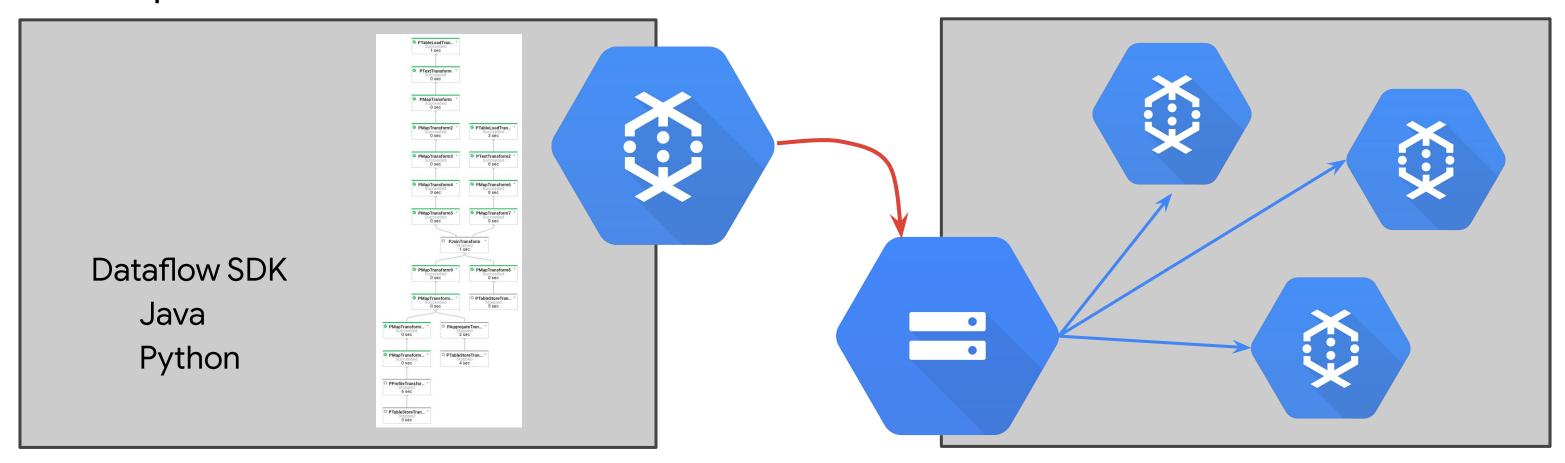

SDK stages files in Cloud Storage Developer or User submits source code to run Dataflow jobs

Template workflow supports non-developer users

Development environment

Production environment

Developer creates pipeline in the development environment Dataflow stores template in cloud storage Users submit templates to run jobs

Get started with Google-provided templates

Pre-written Cloud Dataflow pipelines for common data tasks that can be triggered with a single command or UI form.

Target users

Exposure

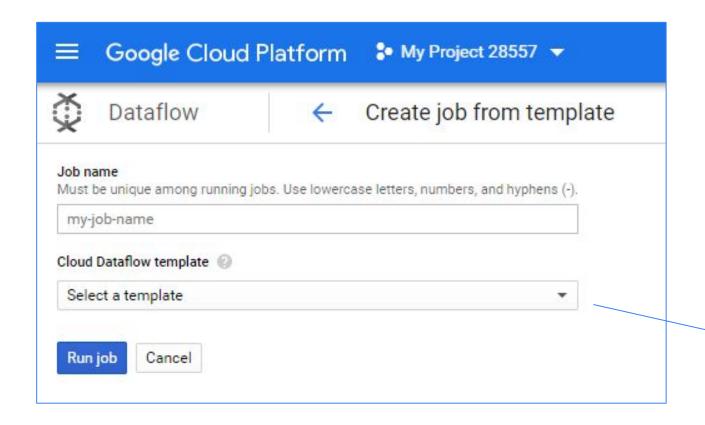

Data Fusion

- App developers
- DB admins
- Analysts
- Data scientists
- Data engineers

- Through Google-provided
 Cloud Dataflow templates
- Embedded in other GCP products calling templates API
- Branded Google product
- UI pipeline builder
- Scheduler/orchestrator

Execute templates with the GCP Console, gcloud command-line tool, or the REST API

gcloud dataflow jobs run \
--gcs-location=gs://df-ts/latest/PubsubToBigQuery \
--parameters inputTopic=X outputTable=Y

Cloud Dataflow > Documentation

Get started with Google-provided templates

Google provides a set of open-source Cloud Dataflow templates. For general information about templates, see the Overview page. To get started, use the WordCount template documented in the section below. See other Google-provided templates:

Streaming templates - Templates for processing data continuously:

- Cloud Pub/Sub Subscription to BigQuery
- Cloud Pub/Sub Topic to BigQuery
- Cloud Pub/Sub to Cloud Pub/Sub
- Cloud Pub/Sub to Cloud Storage Avro
- Cloud Pub/Sub to Cloud Storage Text
- Cloud Storage Text to BigQuery (Stream)
- Cloud Storage Text to Cloud Pub/Sub (Stream)
- Data Masking/Tokenization using Cloud DLP from Cloud Storage to BigQuery (Stream)

Batch templates - Templates for processing data in bulk:

- Cloud Bigtable to Cloud Storage Avro
- Cloud Bigtable to Cloud Storage SequenceFiles
- Cloud Datastore to Cloud Storage Text
- Cloud Spanner to Cloud Storage Avro
- Cloud Spanner to Cloud Storage Text
- Cloud Storage Avro to Cloud Bigtable

Use cases of Google-provided templates

- Code-free routine job launcher for data engineers
- Building block for import/export feature of other services on GCP
- OSS code base works as good knowledge base

Which means now you can...

- Launch Dataflow jobs programmatically (via API).
- Launch Dataflow jobs instantaneously.
- Re-use Dataflow jobs
- Letting you customize the execution of your pipeline

What if you want to create your own template?

- Doc: https://cloud.google.com/dataflow/docs/templates/overview
- Steps
 - 1. Modify pipeline options with ValueProviders.
 - 2. Generate template file.

3. Call it from API.

```
POST https://dataflow.googleapis.com/v1b3/projects/[YOUR_PROJECT_ID]/templates:launch?gcsPath **est://
{
    "jobName": "[JOB_NAME]",
    "parameters": {
        "inputFile": "gs://[YOUR_BUCKET_NAME]/input/my_input.txt",
        "outputFile": "gs://[YOUR_BUCKET_NAME]/output/my_output"
    },
    "environment": {
        "tempLocation": "gs://[YOUR_BUCKET_NAME]/temp",
        "zone": "us-central1-f"
    }
}
```

Templates require modifying parameters for runtime

```
Python
class WordcountOptions(PipelineOptions):
    @classmethod
    def add argparse args(cls, parser):
                                                     Run-time
      parser.add value provider argument ( <---
                                                     parameters
          '--input',
          default='gs://dataflow-samples/shakespeare/kinglear.txt',
          help='Path of the file to read from')
      parser.add argument(
                                                    Non run-time
          '--output',
                                                    parameters can stay
          required=True,
          help='Output file to write results to.')
 pipeline options = PipelineOptions(['--output',
'some/output path'])
  p = beam.Pipeline(options=pipeline options)
 wordcount options = pipeline options.view as(WordcountOptions)
 lines = p | 'read' >> ReadFromText(wordcount options.input)
```

Runtime parameters must be modified

Creating a template

- ValueProviders are passed down throughout the whole pipeline construction phase
- ValueProvider.get() only available in processElement()
 - Because it is fulfilled via API call

```
public interface SumIntOptions extends PipelineOptions {
    // New runtime parameter, specified by the --int
   // option at runtime.
   ValueProvider<Integer> getInt();
   void setInt(ValueProvider<Integer> value);
class MySumFn extends DoFn<Integer, Integer> {
   ValueProvider<Integer> mySumInteger;
    MySumFn(ValueProvider<Integer> sumInt) {
       // Store the value provider
        this.mySumInteger = sumInt;
    @ProcessElement
    public void processElement(ProcessContext c) {
       // Get the value of the value provider and add it to
       // the element's value.
      c.output(c.element() + mySumInteger.get());
public static void main(String[] args) {
 SumIntOptions options =
        PipelineOptionsFactory.fromArgs(args).withValidation()
          .as(SumIntOptions.class);
```

Nested Value Providers

```
nublic_static void main(String[] args) {
  nineline
    .applv(Create.of(1, 2, 3).withCoder(BigEndianIntegerCoder.of()));
    // Write to the computed complete file path.
    .applv("OutputNums", TextIO.write().to(NestedValueProvider.of()
      options.getFileName().
      new SerializableFunction<String, String>() {
        @Override
        public String apply(String file) {
          return "gs://bucket/" + file;
     })));
 pipeline.run();
```

Template Metadata

Located at the same directory, named <template_name>_metadata

```
"name": "WordCount",
"description": "An example pipeline that counts words in the input file.",
"parameters": [{
  "name": "inputFile",
  "label": "Input Cloud Storage File(s)",
  "help_text": "Path of the file pattern glob to read from.",
  "regexes": ["^gs:\/\/[^\n\r]+$"],
  "is_optional": true
 "name": "output",
  "label": "Output Cloud Storage File Prefix",
  "help_text": "Path and filename prefix for writing output files. ex: gs://MyBucket/counts",
  "regexes": ["^gs:\/\/[^\n\r]+$"]
}]
```
